Abstract: The fish fauna of Zarivar lake, Iran is reviewed. Fourteen fish species are reported, five of them native and nine alien to the Euphrates and Tigris drainages. During a survey of the lake in 2009, nine fish species could be recorded, that all of them non native. No native species could be found at all. Furthermore, we report here the first occurrence of the East Asian cyprinid Hemiculter leucisculus and the Caspian cyprinid Alburnus hohenackeri from Tigris drainage both most likely having been introduced from the Caspian Sea basin.

Key words: Alien species, ichthyofauna, Cyprinidae, Zarivar, Iran
Accepted: 1st march, 2011

Introduction
Zarivar (Zeribar) lake (Figure 1) is situated within the Tigris drainage at 1,285 meters above the sea level and is one of the biggest freshwater lakes of the Kurdistan Province in Iran. It is an important wetland with about 750 ha, an average water depth of 4.5 meters and a water volume of 22 to 47 million cubic meters; its water originates mostly from springs at the lake bottom (Jalali and Barzegar 2006). While the introduction of freshwater fish species to Iran dates back to the 1920s (see recent reviews by Coad 2010 and Esmaeili et al. 2010), introduction of fishes to the lake Zarivar have been started in 1982 by the local Fisheries Company with the aim of improving commercial fisheries (Jalali and Barzegar 2006). Our knowledge concerning the ichthyofauna of this lake is limited to fish parasitic studies carried out by Jalali et al. (2001; 2002; 2005; 2008), Jalali and Barzegar (2006) and Shamsi et al. (2009) also recording some fish species from the lake.

Visiting the lake in 2009, we aim to update the knowledge on the fishes of Zarivar Lake and report our findings.

Materials and Methods
The present study is based on previous records and new collections made by the authors applying gillnet, hand net and hook and line fishing at Zarivar Lake (35°32’N, 46°08’E) during three days field work in June 2009. We also surveyed the catches of local fishermen and also the fish market in the Marivan City. Voucher specimens were preserved in 10% formalin in the field and deposited in the Collection of Biology Department, Shiraz University (ZM-CBSU). Fishes were identified based on morphological and meristic characters.
Results
The ichthyofauna of Zarivar lake based on previous reports and our recent visit is listed in Table 1. Five native and nine alien species have been recorded. In June 2009, *Alburnus hohenackeri* was the most abundant species recorded by us. *Hemiculter leucisculus* (Figure 2) and *Alburnus hohenackeri* (Figure 3) are recorded for the first time from Tigris drainage.

Discussion
To date 14 fish species have been recorded from Zarivar lake (Table 1). The majority of these (9 species) species are not native to the lake or to the Tigris drainage.

Native species recorded before as *Capoeta barroisi*, *Barbus lacerta*, *Mastacembelus mastacembelus* and *Squalius lepidus* have not been found during our study at Zarivar lake. These species might be extirpated from the lake or they are actually very, very rare.

Some of the previously reported fishes are very likely to have been the victim of misidentifications. Records of *Carassius carassius* and *Gambusia affinis* by Jalali and Barzegar (2006) most likely report to *C. gibelio* and *G. holbrooki*. All reports of *C. carassius* in Iran by Armantrout (1980) and Abdi (1999) need confirmation and it is very likely that this species has to be excluded from...

</table>
the fauna of Iran and all records are mis-
identified C. gibelio or C. auratus (Coad 2010). Jalali and Barzegar (2006) recorded Barbus cyclolepis from the lakes outflow. Barbus cyclolepis is endemic to the European Aegean Sea and Black Sea basins (Greece, Bulgaria, Turkey) (Kottelat and Freyhof 2007). In Tigris drainage, only one Barbus species is known, B. lacerta, which is superfi-
cially similar to B. cyclolepis and was most likely misidentified as this species.

Fishes identified as Chalcalburnus sp. by Jalali and Barzegar (2006) are most likely the bleaks which we identified here as Albunum hohenackeri. This species is widely identified as A. alburnus in Iranian literature (Kiabi et al. 1999; Abdoli and Naderi 2009; Coad 2010). Bogutskaya and Naseka (2004), Kottelat and Freyhof (2007) and Naseka and Bogutskaya (2009) recognize A. hohenackeri as a distinct species. Albunum alburnus is absent from Iran and has to be deleted from the fauna of this country. Albunum hohenackeri is very abun-
dant in the lake and a dominant species of the fish community. Coad (2010) presented a map of the occurrence of A. alburnus in Iran indicating a wide distribution of this species in the Tigris drainage. Obviously, a bleak similar or identical to A. hohenackeri exist also in other parts of the Tigris drainage. Some care should be taken by identifying such fishes as the picture shown by Coad (2010) as A. alburnus most likely represent A. caeruleus, another bleak being widespread and very abundant at least in upper Tigris drainage in Turkey and expected to occur in Iran also. Both species are immediately distinguished by a plain si-
very lateral body coloration in A. hohenackeri (vs. dusty grey with dark gray individual or patches of scales in A. caeruleus).

The East Asian cyprinid H. leuciscus has been recorded from several localities in the southern Caspian Sea basin (Abbasi et al. 1999; Kiabi et al. 1999; Abdoli 2000; Gasm and Mirzaei 2004; Patimar et al. 2002a, 2002b, 2008; Patimar 2008). It also occur in the Tedzhen River in Turkmenistan and there-
fore might also be found in the Tedzhen (= Hari) River drainage of Iran (Coad 2010). This is the first record of this species in the Tigris drainage and we speculate that this might be the starting point of an invasion of the whole drainage system by this species. Ac-
tually, H. leuciscus seems to be still very rare in the lake and only one individual could be recorded. Hemiculter leuciscus and A. hohenackeri both occur in the Iranian Caspian Seabasin and are very likely to have been im-
ported from this area to Zarivar lake together with commercial fish species as Cyprinus car-
pio, Hypophthalmichthys molitrix, H. nobilis and Ctenopharyngodon idella. It should also be noted, that the Chinese carps C. idella, H. molitrix and H. nobilis are only found in the lake due to permanent stocking activities as these species do not find appropriate spawning possibilities in the lake. Young fishes for this permanent stocking do not originate from local artificial breeding facilities but fingerlings are imported from Caspian Sea basin. This practice is a permanent open gate for all un-
wanted alien species to reach into Zarivar Lake.

Acknowledgements

We thank to A. Teimori and Gh. Kamran for their valuable help in fish collections, Shi-
riz University for financial support and Envi-
ronmental Department of Kurdistan province especially Environmental Department of Ma-
river City for their collaboration.
